Houston, Texas

EXECUTIVE SUMMARY

This LiDAR project is to provide high accuracy calibrated multiple returns LiDAR for 197 square miles (510 square kilometers) representing Dewberry's Channel Islands ARRA LiDAR Task Order, off the shore of Santa Barbara, California.

The LiDAR data was acquired and processed by Terrapoint USA. The deliverable products were calibrated raw LiDAR points and associated reports. All elevation products were acquired and processed to meet: ***"U.S. Geological Survey National Geospatial Program Base LiDAR Specifications, Version 12".***

All data delivered will meet and exceed Terrapoint's deliverable product requirements as set out by Terrapoint's I-PROVE program.

The elevation data was verified internally, prior to delivery, to ensure it met fundamental accuracy requirements when compared to McGee Static GPS checkpoints. Below is the summary of the test for all islands:

- The LiDAR dataset was tested to 0.067m vertical accuracy at 95 percent confidence level, based on consolidated $RMSE_z$ (0.034m x 1.960) when compared to 25 GPS static check points.

Please note that this report focuses solely on the Terrapoint activities pertaining to the LiDAR component of this project.

All data delivered meets or exceeds Terrapoint's deliverable product requirements as set out by Terrapoint's I-PROVE program.

CHANNEL ISLANDS ARRA LIDAR PROJECT REPORT

1. Introduction

LiDAR data is remotely sensed high-resolution elevation data collected by an airborne collection platform. By positioning laser range finding with the use of 1 second GPS with 100 Hz inertial measurement unit corrections; Terrapoint's LiDAR instruments are able to make highly detailed geospatial elevation products of the ground, man-made structures and vegetation.

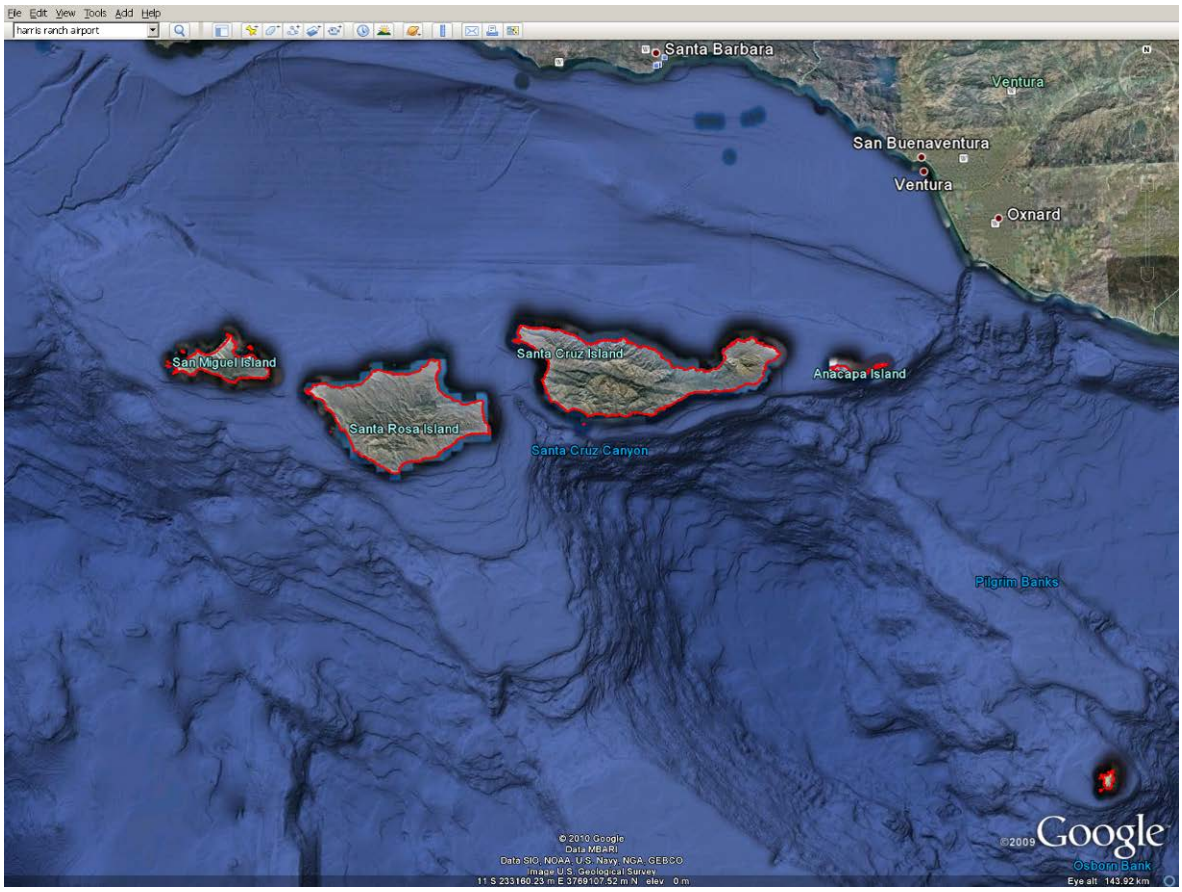
The LiDAR ground extraction process takes place by building an iterative surface model. This surface model is generated using three main parameters: building size, iteration angle and iteration distance.

The purpose of this LiDAR data was to produce high accuracy 3D terrain geospatial products for flood mapping.

This report covers the mission parameters and details, processing step outlines and deliverables.

Please note that this report focuses solely on the Terrapoint activities pertaining to the LiDAR component of this project.

2. Project Boundary



3. LiDAR Acquisition

3.1. Riegl LMS-Q560 Helicopter LiDAR System

Terrapoint used our latest helicopter-based LiDAR sensor. The Riegl LMS-Q560 helicopter-mounted system is designed specifically for small block sites and corridor applications and integrated with the most advanced remote sensing technologies available.

3.1.1. System Details

- Riegl LMS-Q560 Laser Scanner
  - Measurement rate up to 133kHz
  - Full Waveform Recorded for Each Pulse
  - 0.5 mRad Beam Divergence
  - Class 1 eye safe laser
  - 2 to 1000 metres AGL operation
- NovaTel DL-4 L1/L2 GPS Receiver
- IMAR IMU for Precise Georeferencing

3.1.2. The Laser Scanner

The full-waveform Riegl LMS-Q560 is a high-performance eye-safe 2D laser scanner yielding superior density and evenly-distributed ground coverage. Unlike discrete laser sensors, full-waveform analysis gives access to an almost unlimited number of returns per shot and high multiple-target resolution. In other words, features typically not detected by traditional laser scanners are more likely to be detected using the full-waveform as the entirety of each pulse return is recorded to a data recorder. Full waveform LiDAR is also excellent for characterizing vegetation.

Technical Data of *RIEGL* LMS-Q560

Range Measurement Performance

Maximum Measurement Range[1]	*@ Laser PRR*	*50 kHz*	*100 kHz*	*200 kHz*
natural target ρ ≥ 20 %		1200 m	1000 m	700 m
natural target ρ ≥ 60 %		1800 m	1200 m	700 m

Minimum Range	30 m
Accuracy[2]	20 mm
Precision[2]	10 mm
Laser Pulse Repetition Rate[3]	up to 200 000 Hz
Effective Measurement Rate	up to 100 kHz @ 45 deg scan angle up to 133 kHz @ 60 deg scan angle
Laser Wavelength	near infrared
Laser Beam Divergence[4]	≤ 0.5 mrad
Number of targets per pulse	unlimited for digitized waveform[5], first pulse or last pulse in online monitoring data
Eye Safety Class	CLASS 1 LASER PRODUCT according to IEC60825-1:1993+A1:1997+A2:2001 The following clause applies for instruments delivered into the United States: Complies with 21 CFR 1040.10 and 1040.11 except for deviations pursuant to Laser Notice No. 50, dated July 26, 2001.

Scanner Performance

Scanning Mechanism	rotating polygon mirror
Scan Pattern	parallel scanning lines
Scan Angle Range[6]	± 22.5 deg = 45 deg total
Scan Speed	10 - 160 scans/sec
Angle Step Width $\Delta\vartheta$[3] between consecutive laser shots	$\Delta\vartheta \geq$ 0.004 deg (@ PRR 100 000 Hz[7])
Angle Readout Resolution	0.001 deg

Intensity Measurement

For each echo signal, high-resolution 16-bit intensity information is provided which can be used for target discrimination and/or identification/classification.

3.1.3. Positioning and Attitude Systems

The Novatel DL-4 is a high performance, high accuracy, GPS receiver with fast data update rates and integrated memory for data logging. The DL-4 is capable of receiving and tracking the L1 C/A code, L1 and L2 carrier phase and L2 P-Code (or encrypted Y-Code) of up to 12 satellites. Patented Pulsed Aperture Correlator (PAC) technology combined with a powerful microprocessor make possible multipath-resistant processing and excellent acquisition and re-acquisition times.

Unlike other positioning and attitude sensors, the iMAR IMU allows our engineers and scientists access to raw inertial data. Commercially available positioning and attitude systems are designed as a "black box" solutions, and the accuracy and quality of the solution is left to the mercy of the "black box" post-processing software. In combination with the iMAR IMU data and our proprietary GPS-INS post processing software, aircraft trajectories

can be generated using a combination of approaches, weighting GPS and INS measurements according to their quality in tightly-coupled or loosely-coupled Kalman filters.

3.1.4. LiDAR System Parameter Overview

Scan Settings Point Spacing	**PRF (kHz)**	**(kHz)**	100
	Effective	**(kHz)**	67
	Optimal Height AGL	**(m)**	600
	Aircraft Speed	**(kts)**	50
	Scan Angle	**(Degrees)**	60
	Scan Rate	**(Scans/Sec)**	50
	Swath Width	**(m)**	692
	Flight Line Spacing	**(m)**	343
	Laser Spot Diameter	**(m)**	0.3
Scan Settings	**Along Track**	**(m)**	0.51
	Across Track	**(m)**	0.52
	PRF (kHz)	**(kHz)**	100
Point Density	**Nominal Single Swath**	**(Pts/m2)**	3
	With 50% overlap	**(Pts/m2)**	7

3.2. Aircraft

The aircraft used for the survey was a Bell 206 Jet Ranger, registration N49643 with an endurance of approximately 3 hours.

3.3. Base Station and Control GPS Receivers

California Continuously Operating Reference Stations (CGPS) stations were used exclusively to support the airborne operations of this survey and to establish the GPS control network.

3.4. Missions Statistics

Block	Origin	Mission Name	Calendar Date	Number of LiDAR Production Lines
Santa Barbara/Anacapa	**BAR1/ANA1**	M110070A	11-Mar	11
Anacapa	**ANA1**	M110071A	12-Mar	6

			LiDAR missions	197
Totals			**LiDAR Production Lines**	24

LiDAR flightlines were flown in a multiple orientation block designed to best optimize flying time considering the layout for the islands. A graphical representation of the planned flightlines and trajectories are located in Appendix A. A copy of the mission logs can be found in Appendix C

3.5. Horizontal and Vertical Reference Coordinate System Used

Five CGPS were observed in a GPS control network by McGee Surveying and used to control all flight missions and McGee Surveying static ground surveys. The published horizontal datum of the stations is

NAD83 (2007 Epoch) and the vertical datum is NAVD88. The following are the final coordinates of the control points used in this project:

Block	Station	Latitude (D M S Hem)	Longitude (D M S Hem)	H-Ell (m)
Santa Barbara	**BAR1**	33.480451	-119.029735	14.8146
Anacapa	**ANA1**	34.015005	-119.363468	22.4411
Santa Cruz	**CRU1**	34.029259	-119.78481	702.1957
Santa Rosa	**SRS1**	34.004335	-120.065219	68.2316
San Miguel	**MIG1**	34.038258	-120.35139	130.9455

The projection used for all deliverables was UTM 10 and 11 (Natural Zone) and units are meters. The breakdown of zones per island is as follows:

Block	UTM Zone
Santa Barbara	11
Anacapa	11
Santa Cruz	11
Santa Rosa	10 + 11 (two complete deliverable sets)
San Miguel	10

3.6. Geoid Model Used

All elevations were referenced to the GEOID09 model, published by the National Geodetic Survey (NGS), was used to reduce all ellipsoidal heights to orthometric.

3.7. Data Coverage

On a mission and project level, a daily coverage check is performed in the field as per Terrapoint I-Prove requirements.

4. LiDAR Processing

4.1. Airborne GPS Kinematic

Airborne GPS kinematic data was processed on-site using GrafNav kinematic On-The-Fly (OTF) software. Flights were flown with a minimum of 6 satellites in view (13° above the horizon) and with a

PDOP of better than 4. Distances from base station to aircraft were kept to a maximum of 20km.

For all flights, the GPS data can be classified as excellent, with GPS residuals of 3cm average or better but no larger than 10cm being recorded.

4.2. Generation and Calibration of Laser Points (raw data)

The initial step of calibration is to verify availability and status of all needed GPS and Laser data against field notes and compile any data if not complete.

Laser data points are generated using Terrapoint's proprietary laser post-processing software. This software combines the raw laser range and angle data file with the finalized GPS/IMU information. The resulting point cloud has been projected into the desired coordinate system in LAS binary format. All missions are validated against the adjoining missions for relative vertical biases and collected GPS kinematic and static ground truthing points for absolute vertical accuracy purposes.

On a project level, a supplementary coverage check is carried out, to ensure no slivers not found or reported by Field Operation are present.

4.3. Vertical Bias Resolution

The following vertical biases were detected in LiDAR data when compared to the GPS kinematic and static points.

Mission	Lines	Vertical Adjustment
m110073a	All lines	+0.07m
m110074a	All lines	+0.05m
m110075a	line 7404	+0.05m
m110077a	All lines	+0.05m

4.4. Data Classification and Editing

The data was processed using the software TerraScan, and following the methodology described herein. The initial step is the setup of the TerraScan project, which is done by importing project defined tile boundary index encompassing the entire project areas. The acquired 3D laser point clouds, in LAS binary format, were imported into the TerraScan project and divided into file size optimized tiles. Once tiled, the laser points were classified using a proprietary routine in TerraScan. This routine removes any obvious outliers from the dataset following which the ground layer is extracted from the point cloud. The ground extraction process encompassed in this routine takes place by building an iterative surface model.

This surface model is generated using three main parameters: building size, iteration angle and iteration distance. The initial model is based on low points being selected by a "roaming window" with the assumption is that these are the ground points. The size of this roaming window is determined by the building size parameter. The low points are triangulated and the remaining points are evaluated and subsequently added to the model if they meet the iteration angle and distance constraints. This process is repeated until no additional points are added within iteration.

A second critical parameter is the maximum terrain angle constraint, which determines the maximum terrain angle allowed within the classification model.

4.5. Deliverable Product Generation

4.5.1. Deliverable Tiling Scheme

LiDAR deliverables were provided in a 2000mX2000m tiling scheme with a total of 280 tiles (75 duplicates due to Santa Rosa being delivered in both UTm10 and 11).

4.5.2. LAS files

Once the data has been quality controlled and considered complete, the LAS format 1.0 format points are converted to LAS 1.2 Point Data Record Format 1 and the classification scheme, retiled from the USGS Quarter Quad subdivided tiles to the client 2000m x 2000m tiles and converted to the required ASPRS classification scheme (1=Unclassified) from Terrapoint Proprietary classification scheme.

- The following fields within the LAS files are populated to the following precision: Adjusted GPS Time as defined as standard GPS time minus $1*10^9$ (0.000001 second precision), Easting (0.01 foot precision), Northing (0.01 foot precision), Elevation (0.01 foot precision), Intensity (integer value - 12 bit dynamic range), Number of Returns (integer - range of 1-4), Return number (integer range of 1-4), Scan Direction Flag (integer - range 0-1), Classification (integer), Scan Angle Rank (integer), Edge of flight line (integer, range 0-1), User bit field (integer - flight line information encoded).

  The LAS file also contains a Variable length record in the file header.

  Please note that no automated and manual classification was performed on these LAS files from Terrapoint.

  The LAS data tiles were also delivered in strips.

4.5.3. Waveform files

The waveform files were provided in Terrapoint's proprietary format TWF for all missions. A copy of the waveform file structure can be found in Appendix D.

5. Quality Control

5.1. Quality Control for Data Acquisition

The acquisition of overlapping calibration lines for every mission is key to the QC process since it helps identify any systematic issues in data acquisition or failures on the part of the GPS, IMU or other equipment that may not have been evident to the LiDAR operator during the mission.

Ground truth validation is used to assess the data quality and consistency over sample areas of the project. To facilitate a confident evaluation, existing survey control is used to validate the LiDAR data. Published survey control, where the orthometric height (elevation) has been determined by precise differential levelling or GPS observation, is deemed to be suitable.

Ground truth validation points may be collected for each of the terrain categories to establish RMSE accuracies for the LiDAR project. These points must be gathered in flat or uniformly sloped terrain (<20% slope) away from surface features such as stream banks, bridges or embankments. If collected, these points will be used during data processing to test the $RMSE_z$ accuracy of the final LiDAR data products.

The Field Project Manager performs kinematic post-processing of the aircraft GPS data in conjunction with the data collected at the Reference Station. Double difference phase processing of the GPS data is used to achieve the greatest accuracy. The GPS position accuracy is assessed by comparison of forward and reverse processing solutions and a review of the computational statistics. Any data anomalies are identified and the necessary corrective actions are implemented prior to the next mission.

The quality control of LiDAR data and data products has proven to be a key concern by Terrapoint's clients. Many specifications detail how to measure the quality of LiDAR data given RMSE statistical methods to a 95% confidence level. In order to assure meeting all levels of QC concerns, Terrapoint has quality control and assurance steps in both the data acquisition phase and the data processing phase. Any acquired data sets that fail these checks are flagged for re-acquisition.

5.1.1. System Logger – Power Up Health Checks

The system logging software performs automatic system and subsystem tests on power-up to verify proper functionality of the entire data acquisition system. Any anomalies are immediately investigated and corrected by the LiDAR operator if possible. Any persistent problems are referred to the engineering staff, which can usually resolve the issue by telephone and/or email. In the unlikely event that these steps do not resolve the problem, a trained engineer is immediately dispatched to the project site with the appropriate test equipment and spare parts needed to repair the system.

5.1.2. System Logger – Real Time Acquisition Checks

The system logging software continuously monitors the health and performance of all subsystems. Any anomalies are recorded in the System Log and reported to the LiDAR operator for resolution. If the operator is unable to correct the problem, the engineering staffs are immediately notified. They provide the operator with instructions or on-site assistance as needed to resolve the problem.

If any aspect of the data does not appear to be acceptable, the operator will review system settings to determine if an adjustment could improve the data quality. Navigation aids are provided to alert both the pilot and operator to any line following errors that could potentially compromise the data integrity. The pilot and operator review the data and determine whether an immediate re-flight of the line is required.

5.1.3. Post Acquisition Data Check

After the mission is completed, raw LiDAR and imagery data on the removable disk drive is transferred to the Field PC at the field operations staging area. An automated QA/QC program scans the System Log as well as the raw data files to detect potential errors. Any problems identified are reported to the operator for further analysis. Data is also retrieved from all GPS Reference Stations, which were active during the mission and transferred to the Field PC. The GPS data is processed and tested for internal consistency and overall quality. Any errors or limit violations are reported to the operator for more detailed evaluation.

5.1.4. Data Viewer Analysis

The Field Project Manager utilizes a data viewer installed on the Field PC to review selected portions of the acquired LiDAR and imagery data, this permits a more thorough and detailed analysis of the data corrupted files or problems in the data itself are noted. If the data indicates improper settings or operation of the LiDAR sensor and camera, the Field Project Manager determines the appropriate corrective actions needed prior to the next mission.

5.1.5. Data Backup with Redundancy

All LiDAR, imagery and GPS data is copied from the Field PC onto two separate removable hard drives: one for transfer to Calibration, and one for local backup. Each hard drive is reviewed to ensure data completeness and readability.

5.2. Quality Control for Data Processing

Quality assurance and quality control procedures for the raw LiDAR data and processed deliverables for the DEM and derivative products are performed in an iterative fashion through the entire data processing cycle. All final products pass through a six-step QC control check to verify that the data meets the criteria specified by Terrapoint.

The following list provides a step-by-step explanation of the process used by Terrapoint to review the data prior to customer delivery.

5.2.1. LiDAR Calibration

5.2.1.1. Calibration Setup and Data Inventory

Data collected by the LiDAR unit is reviewed for completeness and to make sure all data is captured without errors or corrupted values. In addition, all GPS, aircraft trajectory, mission information, and ground control files are reviewed and logged into a database.

5.2.1.2. Boresight

The LiDAR data is post processed and calibrated as a preliminary step for product delivery initially with default values from the LiDAR system manufacturer or the last mission calibrated for the system. The initial point generation for each mission calibration is

inspected for flight line errors, flight line overlap, slivers or gaps in the data, point data minimums, or issues with the LiDAR unit or GPS. If a calibration error greater than the project specification is observed within the mission, the roll, pitch and scanner scale corrections that need to be applied are calculated. The missions with the new calibration values are regenerated and validated internally once again to ensure quality. Flight line swath overlap is confirmed to the adjacent flight lines at the tolerance specified by the client for overlap throughout the project area thus enabling an evaluation of data reproducibility throughout the areas.

5.2.2. Calibrated Ground Truth Validation

A preliminary $RMSE_z$ error check is performed at this stage of the project life cycle in the raw LiDAR dataset against GPS static and kinematic data and compared to $RMSE_z$ project specifications. The LiDAR data is examined in open, flat areas away from breaks and under specified vegetation categories. This step is repeated in production against the final bare earth LiDAR model.

5.3. LiDAR Production

5.3.1. Production Setup Quality Control

Once the data enters the bare earth extraction stage, a checklist verifying all the components of the project have been received in good order.

5.3.2. Automated Bare Earth Ground Truth Validation

RMSEz is inspected in the automated bare earth model and compared to project specifications. RMSEz is examined in open, flat areas away from breaks and under specified vegetation categories. All accuracy results are reported to the 95% confidence interval for the different categories as available and required. A point comparison of a recently acquired or existing high confidence ground survey point to a TIN generated from the bare earth LiDAR surface. The tolerance for comparisons of control data to the LiDAR TIN elevation is that all sides of the TIN triangle must not be longer than 4.5m to ensure an accurate comparison of surface to the discrete points.

6. Positional Accuracy

6.1. Vertical Positional Accuracy

Prior to delivery the elevation data was verified internally to ensure it met fundamental accuracy requirements when compared to McGee static GPS checkpoints.

- The LiDAR dataset was tested to 0.067m vertical accuracy at 95 percent confidence level, based on consolidated $RMSE_z$ (0.034m x 1.960) when compared to 25 GPS static check points.

6.2. Horizontal Positional Accuracy

Compiled to meet 3.5 foot horizontal accuracy at the 95% confidence level (2 sigma = RMSE * 1.96) in all but extremely hilly terrain.

7. Issues and Resolutions

7.1. Acquisition

7.1.2. Sensor Malfunction

Terrapoint began observing some slight inconsistencies in the mid-range sensor data from Channel Islands, which we believe may be due to a minute change in the characteristics of the laser scanner. Terrapoint has since been monitoring the data quality very closely to ensure it meets the project accuracy requirements. As such, we believe the situation has not degraded since it was discovered, and that the data is meeting the required project specifications.

In summary, Terrapoint has observed instances of "cornrows" in the Channel Island data with the following characteristics:

- The cornrow amplitude is within the 7cm RMSEz specification
- No cornrows greater than 10cm observed
- Observed on all sites throughout the project, however it is only visible on 75% of the terrain
- The cornrows are less visible in Santa Barbara and Anacapa due to steep relief
- More obvious on flat terrain (such as the calibration site at the airport and flat areas of the islands)

Otherwise the data meets the other accuracy requirements of the project:

- Flightline to flightline relative accuracy is better than the required 7cm RMSEz specification requirement
- Absolute accuracy tested at 3cm RMSEz
    - Intensity looks good

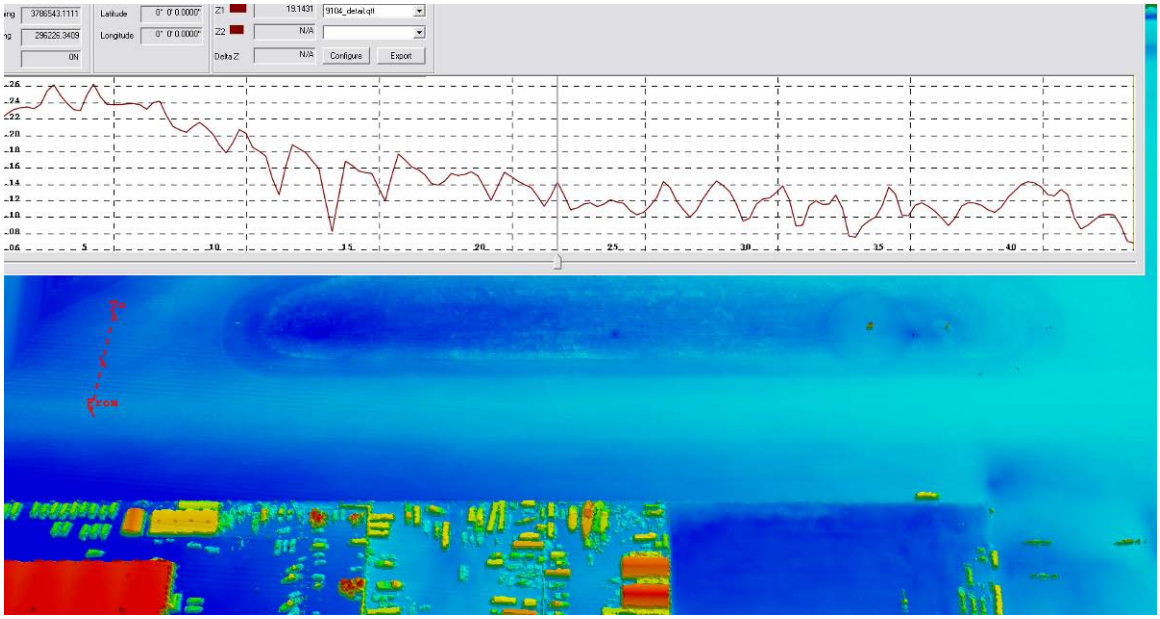
From



The system has since been serviced by Riegl and found The laser polygonal mirror coefficients were off hence the laser required a new internal calibration. It doesn't appear that the laser beam itself degraded. At the time of report submission, Terrapoint has received the repaired system and we are presently in the process of testing the system to ensure no cornrows are being observed.

7.1.3. Project Timeline

The project acquisition stage was longer due to circumstances outside of Terrapoint's control, hence cost overruns were encountered to complete this project; in summary:

At the onset of the project

- this project was priced using our Optech sensor and we changed to the mid-range sensor during the planning phase; this would increase our costs (post contract signing with no opportunity to renegotiate)
- this project was planned without tide restrictions, as discussed during the discovery and proposal/pricing stage of the project (that is, only San Francisco had the tide restrictions)

During the Acquisition Stage of the project

- the tide restrictions precluded long missions, and resulted in more missions to calibrate and process
- the terrain played a factor in acquisition efficiency

- the winds and general weather conditions often precluded flights and/or caused shortened or aborted missions
- extended ferry times increased helicopter costs (no fuel stores on the islands)
- due to the bird migrations etc, we could not land or refuel on the islands, nor fly as low as we would have liked

7.2. Calibration

7.2.2. Project Timeline

Due to the circumstances outlined above in the problems with project acquisition stage; the calibration timelines were also longer due to circumstances mainly outside of Terrapoint's control, hence cost overruns were encountered to complete this project; in summary:

- there were a lot more missions than anticipated due to flight restrictions/shortened missions (see above)
- again, terrain
- calibration hours quadrupled looking into the data issues we found

8. Conclusion

Overall, the LiDAR data products submitted to Dewberry meet or exceed both the absolute and relative accuracy requirements set out in the Statement of Work for this project. The quality control requirements of Terrapoint's I-PROVE program were adhered to throughout the project cycle to ensure product quality.

Appendix A Planned Flight Lines and Trajectories

Appendix D Terrapoint Waveform File Structure

Appendix 1 – Terrapoint Waveform Format file

The Terrapoint Waveform Format, TWF, file is a light-weight simple binary file structure. The file contains a file header record, followed by a data block. The data block consists of multiple waveform records. Each waveform record consists of a waveform header followed by the waveform data. The waveform data consists of low channel data points and high channel data points. The low channel data comes before the high channel data. Each data point is a (range, intensity) pair.

The TWF file header has the following structure:

- Signature -- a 4 byte char containing the TWF file signature -- always "TWFf"
- Major -- the header major version number -- unsigned short (2 bytes)
- Minor -- the header minor version number -- unsigned short (2 bytes)
- HeaderSize -- size of this header record in bytes -- unsigned short (2 bytes)
- NumberOfWaveforms -- the number of waveforms in this TWF file -- unsigned int (4 bytes)
    - For version 1.0, the HeaderSize field will be 14 bytes.

The data block has the following structure:

- 16 byte waveform header record
- Low channel data block
    - (range,intensity) pairs
- High channel data block
    - (range,intensity) pairs

The 16 byte waveform header record has the following structure:

- UTC seconds of day – IEEE double (8 bytes)
- Scan Angle – in degrees – float (4 bytes)
- Number of Lo Channel data points – unsigned short (2 bytes)
- Number of High channel data points – unsigned short (2 bytes)

Each data point has the following structure:

- Range – float (4 bytes)
- Intensity – unsigned short (2 bytes)
